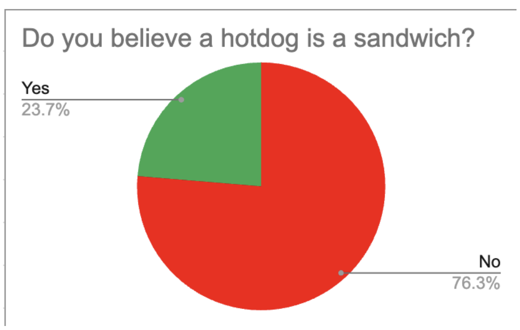
1. **Pre-Analysis Steps**

After retrieving the raw data of the survey from the Google Sheets, we exported the data to an Excel file. Thereafter, we utilized the filter functions to remove any response that did not answer all the questions in the survey. To better reflect the constraints of the hypothesis, we further filtered out responses from individuals who were not full-time undergraduate students. Filtering reduced the number of responses from 79 to 76.

2. **Analysis Method**

For the analysis, we took the cleaned data and built a pie chart to evaluate the responses in a visual way. We also built a Pivot Table from the data, which helps break down the frequency and distribution of the answers based on student year. From this, we were able to see that the older students got, the more likely they are to believe a hotdog is a sandwich. To further scrutinize our visual observations, we ran a chi-square test on our data.

Is a hotdog is a sandwich?	*What year are you?*			
Do you believe a hotdog is a sandwich?	2nd	3rd	4th	Grand Total
No	10	8	40	58
Yes	1	2	15	18
Grand Total	**11**	**10**	**55**	**76**
% No	91%	80%	73%	76%



3. **Evaluation of Success**

To extend our findings statistically, we utilized a chi-squared test within the R stats package. The cell counts were below the minimum recommendations for a chi-square distribution, so we used a Monte Carlo distribution with 100,000 replicates to simulate the p-value. Contrary to our visual observations, we found that the distribution of opinions did not differ significantly between the years (X2 = 1.763, p = 0.439).
