

Pre-analysis would include converting to a .csv file for easier manipulation of the data. We would also need to check if we need to clean the data to make sure there is no null or invalid data that needs to be removed or fixed.

Analysis would include finding out the amount of undergraduate students who think a hot dog is a sandwich vs students who don't think it is one. We could use a one population proportion p test to see if the data we find is statistically significant or not.

The evaluation of success is if after analyzing the data, we compare it to our initial hypothesis of "¼ undergraduate UVA students think that a hot dog is a sandwich". The evaluation would be either true or false.
