Pre-Analysis Steps

We sent out a survey via Google Forms to collect our data. After collecting the raw data, we transferred it into a Google Sheets file. Then, we performed a preliminary search to remove any responses that did not answer all of the questions in the survey (found none as all questions needed to be answered to submit the form). Next, we checked the attendance of students at the university and found that there were three part-time students. We decided to delete these values as they could skew our graphs. Once we completed our cleaning process, the original rows were reduced from 79 to 76. Finally, we converted the data to a csv file to make our analysis easier.

Analysis Methods

Our analysis method for the cleaned data was to go through our data set and visualize the amount of Yes/No responses to whether or not they thought a hot dog was a sandwich as well as what year the respondent was. We decided to analyze the difference in responses in regard to the respondents' year. We also performed a chi squared test to further analyze our results based on year correlation.

Evaluation of Success

Overall, our results supported our original hypothesis. We initially hypothesized that less than 50% of UVA students would say that a hot dog is a sandwich. Our findings showed that 76% of respondents answered “no,” indicating that a strong majority of students do not consider a hot dog to be a sandwich. While this confirms that fewer than half of respondents answered “yes,” the chi-squared test ($p \approx 0.456$) suggests that this opinion does not significantly vary by year and is likely independent of class standing. This exploratory analysis was successful in showing that UVA students tend to agree on this question regardless of year (can see this also in the graphs below), though the lack of first-year respondents and the skew toward upperclassmen suggest that a larger and more balanced sample would be needed for more definitive conclusions.
