

Pre-Analysis Steps:

After collecting the data through Google Forms, we downloaded the raw data as a CSV. Then, for cleaning the data, we dropped the timestamp column and filtered to keep only full time undergraduate UVA students. Additionally, we changed the data type to string for analysis purposes, rather than object. Finally, due to all the questions being responded to, we kept all of the responses.

Analysis Methods:

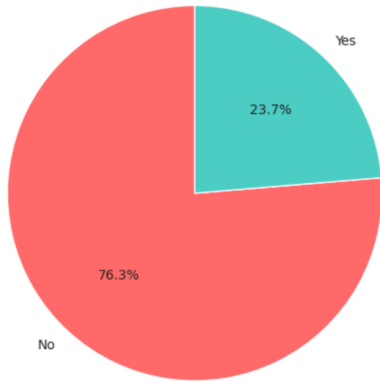

Our analysis methods for the cleaned data began with exploratory graphs in which we could see the total number of Yes and No answers to whether or not somebody considered a hot dog a sandwich overall, and by class year. Moving forward with our analysis, we wanted to examine the distribution of Yes/No answers amongst the different class years.

Evaluation of Success:

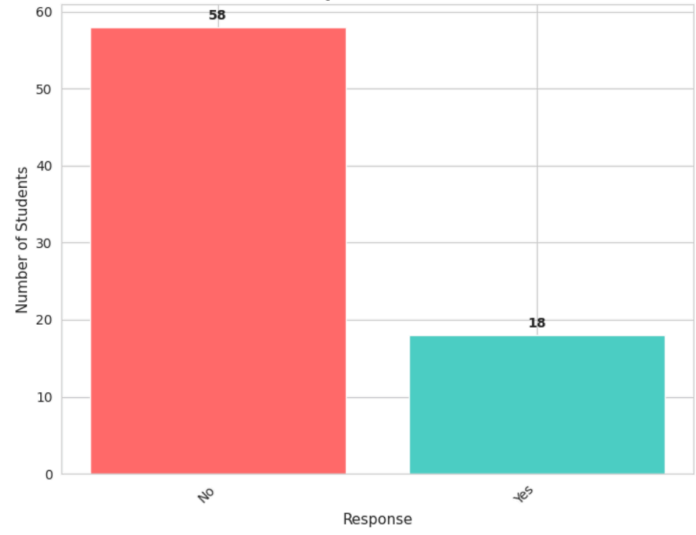

Overall, our analysis of the data was successful; however, these results should be taken with a grain of salt. If we wanted to find a clear correlation, there are many changes we would need to make. First, our sample size was too small; there was only a total of 76 respondents to our survey, which is not representative of the full UVA undergraduate student population.

Furthermore, the survey population was primarily fourth years and did not account for first years. Below are graphs that display the total number of responses across years at UVA.

Overall Opinion Distribution

Response Counts

Sample Distribution by Class Year
